

Ξ Hyperon Photoproduction from Threshold to 5.4 GeV with the CEBAF Large Acceptance Spectrometer

PhD Defense Presentation

John Theodore Goetz

B.M.K. Nefkens, Committee Chair UCLA Dept. Physics & Astronomy

November 1, 2010

Outline of Part I: Cascade Hyperons and g12

Motivation

- The Strong Force
- Cascades (Ξ)
- Photoproduction of Ξ's

2 The g12 Experiment

- The CLAS Detector
- g12 Data and Reconstruction

3 g12 Kaon Data

- Missing Mass Technique
- Missing Mass off K^+K^+
- Sources of Background

Outline of Part II: Results From g12

Title Outline

4 Ξ Excitation Functions

- Calculation Technique
- Simulations and Acceptance
- Ξ Yields and Excitation Functions

5 Search for Higher Mass Ξ*

- Upper Limit Calculation Technique
- Upper Limits

6 Search for Iso-Exotics

- Estimated Sensitivity
- Ξ Iso-Exotics
- Σ Iso-Exotics

7 Conclusions

- Summary
- Future Work
- Specific Issue: g6c plot

< 3

Part I

Cascade Hyperons and the g12 Experiment

The Strong Force Cascades (Ξ) Photoproduction of Ξ's

The Forces of Nature

Four known forces: gravitational, electromagnetic, weak, strong

- The gravitational force is always attractive
- The electromagnetic force can be attractive or repulsive
- The weak force is responsible for neutrino interaction
- The strong force is either attractive or repulsive depending on the range of the particles (quarks)

< 3 >

The Strong Force Cascades (Ξ) Photoproduction of Ξ's

The Forces of Nature

Four known forces: gravitational, electromagnetic, weak, strong

- The gravitational force is always attractive
- The electromagnetic force can be attractive or repulsive
- The weak force is responsible for neutrino interaction
- The strong force is either attractive or repulsive depending on the range of the particles (quarks)

To complicate matters, the particles that interact via the strong force are only found in specific combinations and are never isolated

UCLA

< 回 > < 三 > < 三

Jefferson Lab

The Strong Force Cascades (Ξ) Photoproduction of Ξ 's

Baryons and the Cascades

Quarks spin = 1/2		
Flavor	Approx. Mass GeV/c ²	Electric charge
U up	0.003	2/3
d down	0.006	-1/3
C charm	1.3	2/3
S strange	0.1	-1/3
t top	175	2/3
b bottom	4.3	-1/3

- The strong force is what binds the three quarks inside the proton
- There are six flavors of quarks
- This study involves only the lightest three

 Ξ States are identified by the quantum numbers:

- Baryon = 1
- Strangeness = −2
- $Q \in \{-1, 0\}$

< E

The Strong Force Cascades (Ξ) Photoproduction of Ξ 's

Baryons and the Cascades

In order to study the strong interaction, we look at qqq systems with two strange quarks. They are narrow and SU(3) symmetry suggests a 1:1 correspondence between the Xi spectrum and N/ Δ 's UCLA Jefferson Lab

rator Facility

The Strong Force Cascades (Ξ) Photoproduction of Ξ 's

Previous Investigations

virtually all evidence for Ξ^* states come from measuring the decay particles directly in hadron-production experiments such as:

•
$$K^-p \rightarrow \Xi^-K^+$$

•
$$\Sigma^- p \rightarrow \Xi^0 p K^+$$

photoproduction provides another way to measure the cascades:

$$\gamma p \to \Xi^- \mathrm{K}^+ \mathrm{K}^+$$

The Strong Force Cascades (Ξ) Photoproduction of Ξ 's

Previous Investigations

virtually all evidence for Ξ^* states come from measuring the decay particles directly in hadron-production experiments such as:

•
$$K^-p \rightarrow \Xi^-K^+$$

•
$$\Sigma^- \mathrm{p} \to \Xi^0 \mathrm{pK}^+$$

photoproduction provides another way to measure the cascades:

$$\gamma p \to \Xi^- \mathrm{K}^+ \mathrm{K}^+$$

Photoproduction of Ξ 's

Allows the cascade to be identified by the photon and two K^+ 's

There are a few requirements to this avenue of investigation

- photon (beam) energy measurement
- ${\ensuremath{\, \bullet }}$ four-momenta of the two $K^+\mbox{'s}$
- sufficient acceptance for the kaons
- understanding of sources of background

The CLAS detector at JLab satisfies these requirements

Calibration and Reconstruction

Primary Calibrators

- C. Bookwalter, FSU (TOF)
- P. Eugenio, PhD., FSU (coord)
- J. Goetz, UCLA (recons.)
- L. Guo, PhD., FIU (coord)
- V. Kubarovsky, PhD., JLab (coord)
- M. Paolone, PhD., USC (EC, CC)
- J. Price, PhD., CSUDH (coord)
- M. Saini, FSU (RF, ST, TAG)
- D. Schott, FIU (DC)
- B. Stokes, PhD., GWU (DC)
- A. Vlassov, PhD., JLab (CC)
- D. Weygand, PhD., JLab (coord)
- M. Wood, PhD., Canisius (EC)

Calibration of the g12 data took this team a year and three months.

- My specific role was to ensure the reconstruction of tracks (four-vectors) from the raw data was done correctly and efficiently
- This involved debugging several programs which were developed over two decades by approx. two dozen people using a mix of FORTRAN, C, C++, and various scripting languages

• • = • • = •

The CLAS Detector g12 Data and Reconstruction

Reconstruction - Algorithm

I developed this flowchart of the reconstruction algorithm and the corresponding expansions for tracking in the dissertation

There have been other studies of the reconstruction algorithm used by CLAS, but this is the first I know of that obtained the relative processing time for each step.

Reconstruction - Timeline

The reconstruction of raw data to an analysis-ready "cooked" version took four months using the computing farm at JLab.

- Sept: higher priority
 Oct: increased cache
 Nov & Dec: more
 - CPUs

Analysis Framework

The single-kaon skim we initially made on the data consisted of 30% of the cooked data (about 100 TB)

This made it very difficult to read through quickly.

I developed my own variably-sized ntuple using the Serialization library from the BOOST project in C++

- this effectively converted the cooked data to zipped ASCII files
- resulting single kaon data (from 90 TB) was 1.6 TB

The 1.6 TB can be analyzed in about 1.5 days using our own farm (next door)

< ∃ >

Missing Mass Technique Missing Mass off K^+K^+ Sources of Background

Missing Mass Technique

$$\gamma \mathrm{p} \to \mathrm{K}^+\mathrm{K}^+X^-$$

- since we wish to use the missing mass technique, we must first determine its accuracy by looking at known states.
- For kaon data, we will start with singly strange baryons (Σ 's and Λ 's)
- Note that these data were calibrated mostly with exclusive pion events: $\gamma p \to p \pi^+ \pi^-$

< 回 > < 三 > < 三 >

- $\Xi^{*-} = 1535.2 \pm 0.8$ MeV PDG = 1535.0 ± 0.6
- misidentified pion events show up as vertical bands

Missing Mass Technique Missing Mass off K⁺K⁺ Sources of Background

TOF Energy Deposit Cut

- kaons identified from $\phi(1020)$ and $\Xi^-(1320)$ signals
- number of kaons, pions and protons were normalized in this to bring out the kaon band
- this cut was used as a <u>consistency check</u> of the particle ID which was based on timing

Missing Mass Technique Missing Mass off K⁺K⁺ Sources of Background

Proton Cut

- proton can be used to remove the $\Sigma^-(1189)$ events: $\gamma p \rightarrow \Sigma^- K^+ \pi^+$ $\Sigma^- \rightarrow n\pi^-$ (99.8%)
- affects Σ*⁻ events differently from Ξ*⁻ events since the Ξ*⁻'s are more likely to decay to a proton
- Because the reductions in the Ξ signals and the Σ^{*-} background are different, this is a direct test of the measurements of the events in the peaks

Missing Mass Technique Missing Mass off K⁺K⁺ Sources of Background

Proton Cut

- proton can be used to remove the $\Sigma^{-}(1189)$ events: $\gamma p \rightarrow \Sigma^{-} K^{+} \pi^{+}$ $\Sigma^{-} \rightarrow n\pi^{-}$ (99.8%)
- affects Σ^{*−} events differently from Ξ^{*−} events since the Ξ^{*−}'s are more likely to decay to a proton

• Because the reductions in the Ξ signals and the Σ^{*-} background are different, this is a direct test of the measurements of the events in the peaks

Missing Mass Technique Missing Mass off K^+K^+ Sources of Background

Sources of Background

Two types of background sources in $MM(K^+K^+)$ distribution

Inefficiencies

- misidentified particles (pions are ID'd as kaons)
 - Σ^{*-} states contributed through this and is the largest source of background in this analysis
- wrong beam energy from the tagger

Competing Physics

- Possibility of many high-mass, broad Ξ^{*-} states
- Y^* pion emission (soft π^0 's)
- neutral kaon channels such as: $\begin{array}{l} \gamma p \rightarrow Y^* K^+ \\ Y^* \rightarrow \Xi^{*0} K^{*0} \\ K^{*0} \rightarrow K^+ \pi^- \end{array}$

Calculation Technique Simulations and Acceptance Ξ Yields and Excitation Functions

Model Dependence and Systematic Uncertainty

The model used to simulate Ξ events is the largest source of $\ensuremath{\text{systematic}}$ uncertainty.

- The model used was a t-channel production of a Y* which then decayed by phase-space to the Ξ
- The major parameters we adjusted to get good agreement with the kaon distributions seen in the data were:
 - *t*-slope of the leading K^+
 - mass of the Y^{*}
 - width of the Y*

Calculation Technique Simulations and Acceptance E Yields and Excitation Functions

Extracting Yields from the Data

- 3rd order polynomial
- Gaussian peak
- yield is the integral of the <u>histogram</u> minus the integral of the <u>polynomial part</u> of the total fit.
- There is a systematic uncertainty in this fit
- The shape of the background is not known, but only approximated by the low-order polynomial
- The proton cut gives us a handle on the systematics of this fit indirectly (discussed later)

 $\Xi^-(1320)$ fit, full statistics

Calculation Technique Simulations and Acceptance E Yields and Excitation Functions

Extracting Yields from the Data

- 3rd order polynomial
- Gaussian peak
- yield is the integral of the <u>histogram</u> minus the integral of the <u>polynomial part</u> of the total fit.
- There is a systematic uncertainty in this fit
- The shape of the background is not known, but only approximated by the low-order polynomial
- The proton cut gives us a handle on the systematics of this fit indirectly (discussed later)

 $\Xi^-(1320)$ fit, full statistics

Sensitivity of Yield Measurement

Upper Limit Calculation Technique Upper Limits

Sensitivity of Yield Measurement

Upper Limit Calculation Technique Upper Limits

Sensitivity of Yield Measurement

- Upper Limit Calculation same as that for Excitation Function I win calc
 Differences:
 - Instead of yield, we have the sensitivity to measured yield
 - dependent on the width searched for (25-30 was used for the Ξ^*)
 - acceptance similar to Xi(1530)
 - can't adjust simulation parameters to a signal since there is none!

(B)

Summary Future Work Specific Issue: g6c plot

Summary

• higher mass Y^* 's contribute to Ξ production at higher CM energies

- photoproduction total cross sections for the Ξ^{*-} states above 1530 MeV are smaller than anticipated (no higher than 2 nb)
- This is consistent with the "vector meson dominance" model of the photon (see Fig. 17 on page 20 of dissertation) where the production ratio means we expect 75 events for the $\Xi^{*-}(1690)$ in g12 we are only sensitive to about 250 events

above comparison breaks down due to the difference in beams:

 Σ^- beam vs. γ beam

but it is the only type of measurement available

• no evidence for iso-exotic baryons of strangeness -1 or -2 (estimated sensitivity \approx 10–100 nb)

< 回 > < 回 > < 回 >

Summary Future Work Specific Issue: g6c plot

Possible Future Work

- Ξ^- and Ξ^{*-} differential cross section measurement (requires work on the simulation model used)
- Ξ^0 differential and total cross section (neutral kaon channel)
- Ω^- photoproduction (never seen!)
- mapping out accurate upper limits for the iso-exotics as functions of mass and width

Summary Future Work Specific Issue: g6c plot

$\Xi(1530)$: $\Xi(1690)$ ratio in kaon production

- Invariant mass of Ξ⁻π⁺ using the Σ⁻ beam at CERN from Adamovich et al., 1997
- this measured ratio equates to \geq 75 \equiv (1690) events in g12 data
- only experimental evidence that a factor of 10 more statistics would be enough to observe the \u00e4(1690)

Summary Future Work Specific Issue: g6c plot
